FORECASTING PRINCIPLES AND PRACTICE

7. Time series regression models

7.1 The linear model

OTexts.org/fpp3/

Multiple regression and forecasting

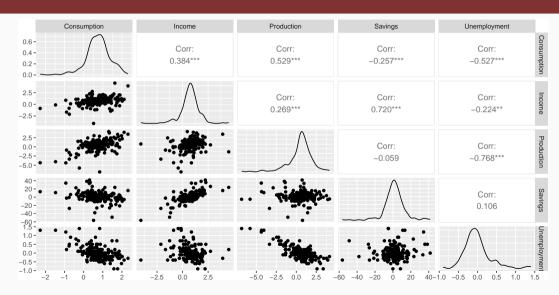

$$\mathbf{y}_t = \beta_0 + \beta_1 \mathbf{x}_{1,t} + \beta_2 \mathbf{x}_{2,t} + \cdots + \beta_k \mathbf{x}_{k,t} + \varepsilon_t.$$

- y_t is the variable we want to predict: the "response" variable
- Each $x_{j,t}$ is numerical and is called a "predictor". They are usually assumed to be known for all past and future times.
- The coefficients β_1, \ldots, β_k measure the effect of each predictor after taking account of the effect of all other predictors in the model.

That is, the coefficients measure the **marginal effects**.

 $\mathbf{\varepsilon}_t$ is a white noise error term

```
fit_consMR <- us_change |>
  model(lm = TSLM(Consumption ~ Income + Production + Unemployment + Savings))
report(fit_consMR)
```

```
## Series: Consumption
## Model: TSLM
